Embeddings and generative models

Many applications such as image synthesis, denoising, super-resolution, speech synthesis, compression, etc. require to go beyond classification and regression, and model explicitly a high dimension signal.

This modeling consists of finding "meaningful degrees of freedom" that describe the signal, and are of lesser dimension.

François Fleuret EE-559 – Deep learning / 9.2. Autoencoders 2/19

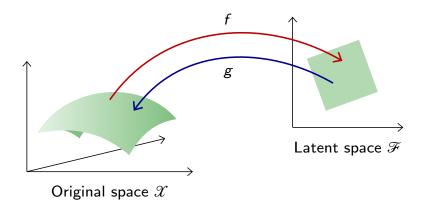

When dealing with real-world signals, this objective involves the same theoretical and practical issues as for classification or regression: defining the right class of high-dimension models, and optimizing them.

Regarding synthesis, we saw that deep feed-forward architectures exhibit good generative properties, which motivates their use explicitly for that purpose.

François Fleuret EE-559 – Deep learning / 9.2. Autoencoders 4 / 19

Autoencoders

An autoencoder (Bourlard and Kamp, 1988; Hinton and Zemel, 1994) combines an **encoder** f from the original space $\mathcal X$ to a **latent** space $\mathcal F$, and a **decoder** g to map back to $\mathcal X$, such that $g \circ f$ is [close to] the identity on the data.

A proper autoencoder has to capture a "good" parametrization of the signal, and in particular the statistical dependencies between the signal components.

François Fleuret EE-559 - Deep learning / 9.2. Autoencoders 6 / 19

Let q be the data distribution over \mathcal{X} . A good autoencoder could be characterized with the quadratic loss

$$\mathbb{E}_{X\sim q}\Big[\|X-g\circ f(X)\|^2\Big]\simeq 0.$$

Given two parametrized mappings $f(\cdot; w)$ and $g(\cdot; w)$, training consists of minimizing an empirical estimate of that loss

$$\hat{w}_f, \hat{w}_g = \underset{w_f, w_g}{\operatorname{argmin}} \frac{1}{N} \sum_{n=1}^{N} \|x_n - g(f(x_n; w_f); w_g)\|^2.$$

A simple example of such an autoencoder would be with both f and g linear, in which case the optimal solution is given by PCA. Better results can be achieved with more sophisticated classes of mappings, in particular deep architectures.

Deep Autoencoders

François Fleuret

 ${\sf EE\text{-}559-Deep\ learning}\ /\ 9.2.\ Autoencoders$

A deep autoencoder combines an encoder composed of convolutional layers, with a decoder composed of the reciprocal transposed convolution layers. *E.g.* for MNIST:

```
AutoEncoder (
  (encoder): Sequential (
    (0): Conv2d(1, 32, kernel_size=(5, 5), stride=(1, 1))
    (1): ReLU (inplace)
    (2): Conv2d(32, 32, kernel_size=(5, 5), stride=(1, 1))
    (3): ReLU (inplace)
    (4): Conv2d(32, 32, kernel_size=(4, 4), stride=(2, 2))
    (5): ReLU (inplace)
    (6): Conv2d(32, 32, kernel_size=(3, 3), stride=(2, 2))
    (7): ReLU (inplace)
    (8): Conv2d(32, 8, kernel_size=(4, 4), stride=(1, 1))
  (decoder): Sequential (
    (0): ConvTranspose2d(8, 32, kernel_size=(4, 4), stride=(1, 1))
    (1): ReLU (inplace)
    (2): ConvTranspose2d(32, 32, kernel_size=(3, 3), stride=(2, 2))
    (3): ReLU (inplace)
    (4): ConvTranspose2d(32, 32, kernel_size=(4, 4), stride=(2, 2))
    (5): ReLU (inplace)
    (6): ConvTranspose2d(32, 32, kernel_size=(5, 5), stride=(1, 1))
    (7): ReLU (inplace)
    (8): ConvTranspose2d(32, 1, kernel_size=(5, 5), stride=(1, 1))
 )
)
```

Decoder

Tensor sizes / operations

 $8\!\times\!1\!\times\!1$ $\times 1$ nn.ConvTranspose2d(8, 32, kernel_size=4, stride=1) $32 \times 4 \times 4$ nn.ConvTranspose2d(32, 32, kernel_size=3, stride=2) • • • • $32 \times 9 \times 9$ nn.ConvTranspose2d(32, 32, kernel_size=4, stride=2) $32 \times 20 \times 20$ $\times 20$ nn.ConvTranspose2d(32, 32, kernel_size=5, stride=1) •••••• $32\times24\times24$ $\times 24$ nn.ConvTranspose2d(32, 1, kernel_size=5, stride=1) $1 \times 28 \times 28$ 5

Training is achieved with quadratic loss and Adam

```
model = AutoEncoder(nb_channels, embedding_dim)
model.to(device)

optimizer = optim.Adam(model.parameters(), lr = 1e-3)

for epoch in range(args.nb_epochs):
    for input, _ in iter(train_loader):
        input = input.to(device)

    z = model.encode(input)
    output = model.decode(z)
    loss = 0.5 * (output - input).pow(2).sum() / input.size(0)

    optimizer.zero_grad()
    loss.backward()
    optimizer.step()
```

X (original samples)

$$g \circ f(X)$$
 (CNN, $d = 8$)

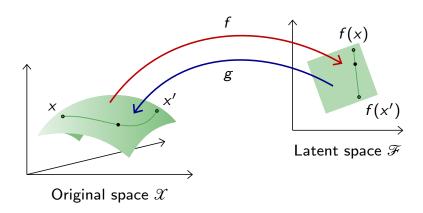

$$g \circ f(X)$$
 (PCA, $d = 8$)

François Fleuret

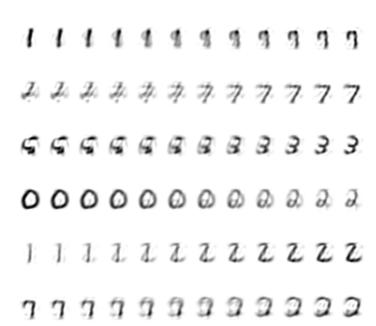

To get an intuition of the latent representation, we can pick two samples x and x' at random and interpolate samples along the line in the latent space

$$\forall x, x' \in \mathcal{X}^2, \ \alpha \in [0, 1], \ \xi(x, x', \alpha) = g((1 - \alpha)f(x) + \alpha f(x')).$$

François Fleuret EE-559 - Deep learning / 9.2. Autoencoders 14 / 19

PCA interpolation (d = 32)

François Fleuret

Autoencoder interpolation (d = 8)

François Fleuret

EE-559 – Deep learning / 9.2. Autoencoders

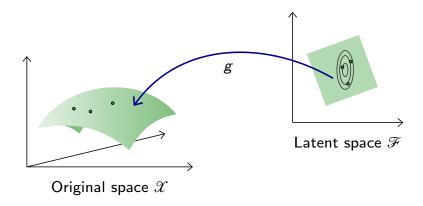

And we can assess the generative capabilities of the decoder g by introducing a [simple] density model q^Z over the latent space \mathcal{F} , sample there, and map the

We can for instance use a Gaussian model with diagonal covariance matrix.

samples into the image space \mathcal{X} with g.

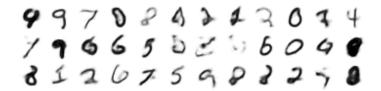

$$f(X) \sim \mathcal{N}(\hat{m}, \hat{\Delta})$$

where \hat{m} is a vector and $\hat{\Delta}$ a diagonal matrix, both estimated on training data.

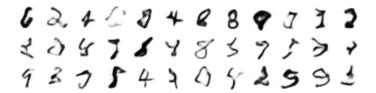

16 / 19

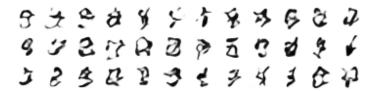

Autoencoder sampling (d = 8)

Autoencoder sampling (d = 16)

Autoencoder sampling (d = 32)

François Fleuret EE-559 – Deep learning / 9.2. Autoencoders 18 / 19

These results are unsatisfying, because the density model used on the latent space \mathcal{F} is too simple and inadequate.

Building a "good" model amounts to our original problem of modeling an empirical distribution, although it may now be in a lower dimension space.
